It was thought possible that, since the Lindera
lanceolata belongs to the same family as the tall ornamental
tree, it may be a derivative of the acid or some acid
closely related to it, and it is for this possibility
in mind that the following tests have been undertaken.

While it is not intended to be too definite until the acid or indeed any acid could fix an uneven number of carbon atoms, nevertheless some very interesting results have been obtained.

hen with the berries have a brilliant red colour, are oval in shape and are about half inch long, and half inch broad. They are attached to the stem by a long pedicel. They are red and white in colour, the red being the outer skin and the white being the flesh. They are then covered with a thin layer of sugar. They are entirely inedible. The berries are allowed to ripen on the tree, and are then picked and dried in the sun.

The berries are used in two ways; first, the extract is made by boiling them in water, and second, the berries are dried and then ground into a powder. The powder was found to be of great value in the treatment of various diseases.

RESUME OF LIFE

The subject of this dissertation was born in Baltimore, Maryland, on the 23rd of April 1875. His early education was obtained in the public schools of Baltimore, and he graduated from the Baltimore City College in 1893. In the fall of 1893 he entered the Johns Hopkins University and after pursuing the physical-chemical course obtained the degree of Bachelor of Arts in June, 1896. Since the fall of 1896 he has been doing graduate work in Chemistry as a major subject, in Geology as a first subordinate and in Mineralogy as a second subordinate. During his residence at Hopkins he has held an ordinary Hopkins scholarship and a University scholarship. In the spring of 1899 he was appointed to a fellowship in Chemistry which he resigned in order to become Professor Penner's assistant.
